

LINEARITY OF REGRESSION FOR WEAK RECORDS, REVISITED

RAFAŁ KARCZEWSKI, JACEK WESOŁOWSKI

ABSTRACT. Since many years characterization of distribution by linearity of regression of non-adjacent weak records $\mathbb{E}(W_{i+s}|W_i) = \beta_1 W_i + \beta_0$ for discrete observations has been known to be a difficult question. López-Blázquez (2004) proposed an interesting idea of reducing it to the adjacent case and claimed to have the characterization problem completely solved. We will explain that, unfortunately, there is a flaw in the proof given in that paper. This flaw is related to fact that in some situations the operator responsible for reduction of the non-adjacent case to the adjacent one is not injective. The operator is trivially injective when $\beta_1 \in (0, 1)$. We show that when $\beta_1 \geq 1$ the operator is injective when $s = 2, 3, 4$. Therefore in these cases the method proposed by López-Blázquez is valid. We also show that the operator is not injective when $\beta_1 \geq 1$ and $s \geq 5$. Consequently, in this case the reduction methodology does not work and thus the characterization problem remains open.

1. INTRODUCTION

The issue of characterization of the common distribution of a sequence $(X_n)_{n \geq 1}$ of iid variables by linearity of regression of records $\mathbb{E}(R_m|R_n) = \beta_1 R_n + \beta_0$ for $m \neq n$ has attracted the attention of researchers since the seventies in the last century, when Nagaraja (1977), assuming that the common distribution of X_n 's is continuous and following methods developed by Ferguson (1967) for order statistics, characterized the triplet of exponential, power and Pareto type distributions in the case $m = n + 1$. In Nagaraja (1988) the case $m = n - 1$ for continuous distribution was solved by reducing the problem to the one for order statistics. As a result another triplet of distributions was characterized. The characterization in the case $m = n + 2$ was done in Ahsanullah and Wesolowski (1998) through reducing the problem to second order ordinary differential equation and a careful look at its probabilistic solutions. The characterization issue for continuous distributions was finally resolved in the general case of linearity of regression for non-adjacent records in Dembińska and Wesolowski (2001) by using integrated Cauchy functional equation in case $m > n$ and in case $m < n$ by reducing the problem to an analogous problem for order statistics, the latter being solved by a similar method earlier in Dembińska and Wesolowski (1998). Since that time the case of continuous parent distribution has been studied further e.g. for generalized order statistics and for other patterns of regression functions. For these and related issues see e.g. López-Blázquez and Moreno-Rebollo (1997), Bieniek and Szyal (2003), Cramer, Kamps and Keseling (2004), Gupta and Ahsanullah (2004), Bairamov, Ahsanullah and Pakes (2005), Bieniek (2007), Bieniek (2009), Yanev (2012) and Ahsanullah and Hamedani (2013), Beg, Ahsanullah and Gupta (2013).

In the case of discrete distribution instead of records (R_n) , which are defined through a strict inequality, it is more natural to consider weak records (W_n) , which are defined by " \geq " relation. That is, a repetition of the last weak record is the next weak record, while for regular records repetitions of records are discarded. In this case, the issue of characterization of the distribution of X_n 's through linearity of regression $\mathbb{E}(W_m|W_n) = \beta_1 W_n + \beta_0$ for $m \neq n$ seems not to be related to the methods developed in the continuous case. In particular, under natural assumption that the support of the common law of X_n 's is a set of the form $\{0, 1, \dots, N\}$ with $N \leq \infty$ we see that in the case of $m < n$, due to monotonicity of (W_n) sequence, we have $\beta_0 = 0$. To the best of our knowledge, under this assumption ($m < n$) the characterization was obtained only in two special cases: $\mathbb{E}(W_1|W_2) = \beta_1 W_2$ for $\beta_1 > 0$ in López-Blázquez and Wesolowski (2001) and $\mathbb{E}(W_m|W_n) = \frac{m}{n} W_n$ in López-Blázquez and Wesolowski (2004).

For the case $m > n$ the characterization of distribution of X_n 's was first given in Stepanov (1994) for $m = n + 1$ with an improvement in Wesolowski and Ahsanullah (2001) - see also related papers Aliev (1998), Danielak and Dembińska (2007), Dembińska and López-Blázquez (2005). The case $m = n + 2$ for $\beta_1 = 1$ was considered in Aliev (2001) and for general β_1 in Wesolowski and Ahsanullah (2001), where an approach

via solution of a non-linear difference equation was applied. In this way a triplet of geometric and negative hypergeometric distributions of the first and second kind was characterized. For the general case $m > n$ López-Blázquez (2004) (we refer to this paper by LB in the sequel) proposed an intriguing idea of reduction of the problem to the adjacent case of $m = n + 1$, for which the solution has been already known. However, as it will be explained below, this interesting approach is not as universal as it is claimed in that paper. It appears that there are some inaccuracies in the proof in the case $\beta_1 \geq 1$, that is when $N = \infty$. When we encountered these inaccuracies we were rather confident that it would be possible to overcome them while preserving this brilliant idea of reduction to the adjacent case $m = n + 1$. As we will see, this can be done only if $0 < m - n \leq 4$. Unfortunately, for higher distances between m and n the idea introduced in LB does not work. Therefore the characterization in the case $m > n + 4$ and $\beta_1 \geq 1$ still remains an open problem.

Finally, let us mention that the issue of characterization of discrete distributions by linearity of regression of ordinary records $\mathbb{E}(R_m|R_n) = \beta_1 R_n + \beta_0$ has also been considered in the literature. If $m > n$ only characterizations of tails of distribution were eventually obtained, see e.g. Srivastava (1979), Kirmani and Alam (1980), Ahsanullah and Holland (1984), Korwar (1984), Rao and Shanbhag (1986), Nagaraja, Sen and Srivastava (1989), Huang and Su (1999). If $m < n$ no elegant characterization seems to be possible, see López-Blázquez and Wesolowski (2004), except the case $m = 1$, $n = 2$, see López-Blázquez and Wesolowski (2001) and Franco and Ruiz (2001).

2. PASSING FROM THE NON-ADJACENT CASE TO THE ADJACENT ONE IS PROBLEMATIC

We consider a sequence (X_n) of iid random variables having the common distribution $\mathbf{p} = (p_k)$ supported on $\{0, 1, \dots, N\}$, $N \leq \infty$. That is, $p_k = \mathbb{P}(X_1 = k)$, and we also write $q_k = \mathbb{P}(X_1 \geq k)$, $k = 0, 1, \dots, N$. For such a sequence, we consider the respective sequence of weak records (W_n) which is defined as follows: Let $T_1 = 1$ and $T_n = \inf\{k > T_{n-1} : X_k \geq X_{T_{n-1}}\}$, $n > 1$. Then $W_n = X_{T_n}$, $n \geq 1$. The joint distribution of the first n weak records can be easily derived as

$$\mathbb{P}(W_1 = k_1, \dots, W_n = k_n) = p_{k_n} \prod_{j=1}^{n-1} \frac{p_{k_j}}{q_{k_j}}, \quad 0 \leq k_1 \leq \dots \leq k_n.$$

Weak records were introduced in Vervaat (1973) and since then are one of important models for ordered discrete random variables. Their basic properties can be found in any monograph on records, e.g., Ch. 2.8 of Arnold, Balakrishnan and Nagaraja (1998), Ch. 16 of Nevzorov (2001) or in Ch. 6.3. of relatively recent monograph Ahsanullah and Nevzorov (2015). It is well-known that weak records form a homogeneous Markov chain with the transition probability of the form

$$\mathbb{P}(W_n = k_n | W_{n-1} = k_{n-1}) = \frac{p_{k_n}}{q_{k_{n-1}}}, \quad k_n \geq k_{n-1} \geq 0.$$

Therefore, for $m < n$

$$\mathbb{P}(W_n = k_n | W_m = k_m) = \sum_{k_m \leq k_{m+1} \leq \dots \leq k_{n-1} \leq k_n} \prod_{i=m}^{n-1} \frac{p_{k_{i+1}}}{q_{k_i}}, \quad k_n \geq k_m \geq 0.$$

For fixed positive integers i, s we will be interested in conditional expectation $\mathbb{E}(W_{i+s}|W_i)$. Therefore we need to assume that \mathbf{p} is such that this conditional expectation is finite. Since the conditional distribution of $W_{i+s}|W_i$ does not depend on i , we will denote the set of distributions \mathbf{p} for which $\mathbb{E}(W_{i+s}|W_i)$ is finite by \mathcal{M}_s .

Let us consider a family C_s of discrete distributions $\mathbf{p} = (p_k)_{k \geq 0} \in \mathcal{M}_s$, concentrated on $\{0, 1, 2, \dots, N\}$ ($N \leq \infty$) with property that if the common law of iid random variables $(X_n)_{n \geq 1}$ belongs to C_s then the regression of weak records $\mathbb{E}(W_{i+s}|W_i)$ is linear. It is known that $C_1 \subseteq C_s$ for all $s \geq 1$. We are interested in the opposite inclusion. In LB it is claimed that the opposite implication holds true, however the proof of this inclusion given in there is not correct. We will explain why it is not correct, then improve the method proposed in LB to show that the inclusion holds true for $s = 2, 3, 4$ and finally we will show that the method fails for $s \geq 5$.

Before we state the result from LB we need to introduce some notation. Let $\mathbf{v} = (v(0), v(1), \dots, v(N)) \in \mathbb{C}^{N+1}$ (for $N = \infty$, $\mathbf{v} = (v(0), v(1), \dots)$). Let us define a linear operator:

$$A : D(A) \longrightarrow \mathbb{C}^{N+1}; \quad Av(l) = \frac{1}{q_l} \sum_{k=l}^N v(k) p_k, \quad l = 0, 1, \dots, N,$$

where

$$D(A) = \{\mathbf{v} \in \mathbb{C}^{N+1} : \sum_{k=0}^N |v(k)| p_k < \infty\}.$$

We also define the domain of composition of operator A with itself since we will need that later on:

$$D(A^m) = \{\mathbf{v} \in D(A) : A^k \mathbf{v} \in D(A) \text{ for } k = 1, \dots, m-1\} \text{ for } m \geq 2,$$

where

$$A^0 \mathbf{v} = \mathbf{v} \text{ and } A^m \mathbf{v} = A(A^{m-1} \mathbf{v}) \text{ for } m \geq 1.$$

Below we present matrix representation of the operator A (which is an infinite matrix when $N = \infty$):

$$A = \begin{bmatrix} p_0 & p_1 & p_2 & \dots & p_N \\ 0 & \frac{p_1}{q_1} & \frac{p_2}{q_1} & \dots & \frac{p_N}{q_1} \\ 0 & 0 & \frac{p_2}{q_2} & \dots & \frac{p_N}{q_2} \\ \vdots & \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & 0 & \dots & \frac{p_N}{q_N} \end{bmatrix}.$$

Note that A is an upper-triangular matrix with nonzero diagonal entries. Let $e_m(l) = \mathbb{E}(W_{i+m} | W_i = l)$. Then, directly from the form of the conditional distribution it follows that

$$(1) \quad \mathbf{e}_{m+1} = A \mathbf{e}_m \text{ for } m = 1, 2, \dots$$

In particular \mathbf{e}_m is in the domain of A , given that \mathbf{e}_{m+1} exists. Now we can state the theorem proposed in LB.

Theorem 2.1. *Let X be a random variable with discrete distribution with support $\{0, 1, 2, \dots, N\}$ ($N \leq \infty$). Let (W_n) be the sequence of weak records built on a sequence (X_n) of iid random variables having the same distribution as X . Assume that for some $i, s \geq 1$*

$$(2) \quad \mathbb{E}(W_{i+s} | W_i) = \beta_0 + \beta_1 W_i,$$

where $\beta_0, \beta_1 \in \mathbb{R}$. Then $\beta_0, \beta_1 > 0$. Let γ_0, γ_1 be unique solutions of

$$(3) \quad \beta_1 = \gamma_1^s, \quad \beta_0 = \gamma_0 \frac{1 - \gamma_1^s}{1 - \gamma_1}.$$

Then

$$(1) \text{ if } 0 < \beta_1 < 1, \text{ then } \frac{\gamma_0}{1 - \gamma_1} \in \mathbb{N}$$

$$X \sim \text{nh}_I \left(1, \frac{\gamma_1}{1 - \gamma_1}, \frac{\gamma_0}{1 - \gamma_1} \right),$$

$$(2) \text{ if } \beta_1 = 1, \text{ then}$$

$$X \sim \text{geo} \left(\frac{1}{1 + \gamma_0} \right),$$

$$(3) \text{ if } \beta_1 > 1, \text{ then}$$

$$X \sim \text{nh}_{II} \left(1, \frac{\gamma_0 + 1}{\gamma_1 - 1}, \frac{\gamma_0}{\gamma_1 - 1} \right).$$

The symbols of distributions above have the following meaning: nh_I is for the negative hypergeometric distribution of the first kind, geo is for the geometric distribution, nh_{II} is for the negative hypergeometric distribution of the second kind (more details on nh_I and nh_{II} laws can be found e.g. in Wesołowski and Ahsanullah (2001)).

We will now recall basic steps in the proof given in LB. Observe, that since $e_s(l) = \mathbb{E}(W_{i+s}|W_i = l)$ is strictly increasing, we have $\beta_1 > 0$ and $\beta_0 = e_s(0) > 0$. Let γ_0, γ_1 be unique solutions of (3). Now, for $m = 1, \dots, s$ we define \mathbf{d}_m through the equality

$$(4) \quad e_m(j) = \gamma_0 \frac{1 - \gamma_1^m}{1 - \gamma_1} + \gamma_1^m j + d_m(j), \quad j = 0, 1, \dots, N.$$

Directly from the definition of \mathbf{d}_m and the assumption that \mathbf{e}_s exists we obtain that \mathbf{d}_m is in the domain of A for $m = 1, \dots, s-1$. From (2) we have that $\mathbf{d}_s = 0$. After easy algebra we obtain

$$(5) \quad \mathbf{d}_{m+1} = \gamma_1^m \mathbf{d}_1 + A \mathbf{d}_m, \quad m = 1, \dots, s-1.$$

From (5) we can obtain that \mathbf{d}_m is in the domain of A^2 for $m = 1, \dots, s-1$ and by iterating (5) we get that \mathbf{d}_1 is in the domain of A^{s-1} . This can be iterated and, consequently,

$$(6) \quad \mathbf{d}_m = B_m \mathbf{d}_1, \quad m = 1, \dots, s, \quad \text{where} \quad B_m = \sum_{k=0}^{m-1} \gamma_1^{m-1-k} A^k.$$

Let us note that A and, consequently, B_m depends on the unknown distribution $\mathbf{p} = (p_n)_{n \geq 0}$. To emphasize this fact, sometimes we will write $B_m^{(\mathbf{p})}$ instead of B_m .

At this stage of argument we read in LB:

Note that B_m is an upper-triangular matrix with nonzero diagonal entries; then B_m has an inverse (even in the infinite case)

This is why, besides the case $N < \infty$ (equivalent to $\gamma_1 \in (0, 1)$), the proof is incorrect. The above statement is false in the case $N = \infty$ (that is $\gamma_1 \geq 1$). Infinite matrices represent linear operators between linear spaces. In general such transformations, which are represented by infinite upper-triangular matrices with nonzero diagonal entries, do not have to be invertible and even injective. As an example consider a linear transformation $B : \mathbb{R}^\infty \rightarrow \mathbb{R}^\infty$ represented by the matrix

$$B = [b_{ij}]_{i,j=0}^\infty ; \quad b_{ij} = \begin{cases} 1 & \text{for } i = j \text{ or } j = i + 1 \\ 0 & \text{otherwise.} \end{cases}$$

Obviously, B is an upper-triangular matrix with nonzero diagonal entries. Let $v = (1, -1, 1, -1, \dots)$. Then $Bv = 0$ and thus B is not injective in \mathbb{R}^∞ , consequently, it cannot be invertible. However, if we consider B as a linear operator on the space of sequences convergent to 0, then B is invertible with B^{-1} being also upper-triangular with n -th row of the form $(0, \dots, 0, 1, -1, 1, -1, \dots)$, where the first 1 is at the position n , $n \geq 1$.

In the next section we will discuss in detail injectivity of the operator B_s defined in (6), which is of crucial importance since the rest of the argument from LB lies in plugging $m = s$ in (6). Since, as it was observed before, $\mathbf{d}_s = 0$, it follows that

$$B_s^{(\mathbf{p})} \mathbf{d}_1 = 0.$$

So if $B_s^{(\mathbf{p})}$ was injective for any $\mathbf{p} \in \mathcal{M}_s$ we would get $\mathbf{d}_1 = 0$ and, consequently,

$$e_1(j) = \gamma_0 + \gamma_1 j \quad \text{for } j = 0, 1, \dots, N.$$

That is, the crucial problem for validity of the proof as suggested in LB is a question of injectivity of $B_s^{(\mathbf{p})}$ for any $\mathbf{p} \in \mathcal{M}_s$.

3. IS THE OPERATOR $B_s^{(\mathbf{p})}$ INJECTIVE?

In this section we will show how injectivity of $B_s^{(\mathbf{p})}$ defined on $D(B_s^{(\mathbf{p})}) = D(A^{s-1})$ depends on s . Let us recall that we are considering here only such distributions \mathbf{p} for which $\mathbb{E}(W_{i+s}|W_i) < \infty$ and, as it has already been mentioned, this condition depends only on s and not on i . First, we will consider operators with domains being subsets of $\mathbb{C}^\infty = \{(x_0, x_1, \dots) : x_k \in \mathbb{C}\}$, the linear space of sequences of complex numbers.

Theorem 3.1. *Let $B_s^{(\mathbf{p})}$ be the operator defined by (6) with $N = \infty$ on a domain $D(B_s^{(\mathbf{p})}) \subset \mathbb{C}^\infty$. Then $B_s^{(\mathbf{p})}$ is injective for any distribution $\mathbf{p} \in \mathcal{M}_s$ iff $s \in \{2, 3, 4\}$.*

Proof. Since $\sum_{k=0}^{s-1} z^k = \prod_{k=1}^{s-1} (z - \lambda_k)$, where $\lambda_k = \cos\left(\frac{2k\pi}{s}\right) + i \sin\left(\frac{2k\pi}{s}\right)$, $k = 1, \dots, s-1$, $s \geq 2$, we can represent the operator B_s in the following way

$$(7) \quad B_s = \prod_{k=1}^{s-1} (A - \gamma_1 \lambda_k I),$$

where I is the identity operator. Thus if $\gamma_1 \lambda_\ell$ is an eigenvalue of A for some $\ell = 1, 2, \dots, s-1$, then B_s is not injective. Indeed, if $\mathbf{x}_\ell \in D(B_s)$ is a respective nonzero eigenvector of $\gamma_1 \lambda_\ell$, then (note that $(A - \gamma_1 \lambda_j I)$ and $(A - \gamma_1 \lambda_k I)$ commute)

$$B_s \mathbf{x}_\ell = \left[\prod_{\substack{k=1 \\ k \neq \ell}}^{s-1} (A - \gamma_1 \lambda_k I) \right] (A - \gamma_1 \lambda_\ell I) \mathbf{x}_\ell = 0.$$

Consequently, B_s is not injective.

Assume now that none of $\gamma_1 \lambda_\ell$, $\ell = 1, 2, \dots, s-1$ is an eigenvalue of A . Then B_s is a composition of injective operators, so B_s must also be injective.

Finally, we conclude that B_s is injective if and only if all $\gamma_1 \lambda_\ell$, $\ell = 1, 2, \dots, s-1$, are not eigenvalues of A .

We will now examine eigenvalues of A which are of the form $\lambda = \gamma_1 \lambda_\ell$. Let $\lambda \in \mathbb{C}$, $\mathbf{x} \in D(A)$, $\mathbf{x} \neq 0$, be such that $A\mathbf{x} = \lambda\mathbf{x}$ which is equivalent to

$$(8) \quad \sum_{j=i}^{\infty} p_j x_j = \lambda x_i q_i \quad \forall i \geq 0.$$

After subtracting the equality for i and $i+1$ sidewise we obtain

$$x_i p_i = \lambda (x_i q_i - x_{i+1} q_{i+1}).$$

Hence we have

$$x_{i+1} = \frac{\lambda q_i - p_i}{\lambda q_{i+1}} x_i \quad \forall i \geq 0.$$

Expanding this recursion gives

$$x_{i+1} = \frac{\lambda q_i - p_i}{\lambda q_{i+1}} \frac{\lambda q_{i-1} - p_{i-1}}{\lambda q_i} \dots \frac{\lambda q_0 - p_0}{\lambda q_1} x_0 \quad \forall i \geq 0.$$

We assumed that $\mathbf{x} \in D(A)$ and $\mathbf{x} \neq 0$ which now, given the expression above and (8) for $i = 0$, implies

$$(9) \quad \lambda \text{ is an eigenvalue of } A \iff \sum_{k=1}^{\infty} |b_k(\lambda)| p_k < \infty \text{ and } 0 = p_0 - \lambda q_0 + \sum_{k=1}^{\infty} b_k(\lambda) p_k,$$

where

$$b_k(\lambda) = \prod_{i=0}^{k-1} \frac{\lambda q_i - p_i}{\lambda q_{i+1}}.$$

Let us denote

$$S_n(\lambda) = \begin{cases} p_0 - \lambda q_0 & \text{for } n = 0 \\ p_0 - \lambda q_0 + \sum_{k=1}^n b_k(\lambda) p_k & \text{for } n \geq 1 \end{cases} \text{ and } S_n^*(\lambda) = \sum_{k=1}^n |b_k(\lambda)| p_k.$$

By an easy induction argument we obtain the following product representation of $S_n(\lambda)$ for $n \geq 1$

$$S_n(\lambda) = (p_0 - \lambda q_0) \prod_{k=1}^n \frac{\lambda q_k - p_k}{\lambda q_k} = (p_0 - \lambda q_0) \prod_{k=1}^n \left(1 - \frac{c_k}{\lambda}\right), \text{ where } c_k = \frac{p_k}{q_k} \in (0, 1).$$

As observed in (9), we have to consider the situation when $\lim_{n \rightarrow \infty} S_n^*(\lambda) < \infty$ and $\lim_{n \rightarrow \infty} S_n(\lambda) = 0$. Note that

$$\lim_{n \rightarrow \infty} S_n(\lambda) = 0 \iff \lim_{n \rightarrow \infty} |S_n(\lambda)|^2 = 0 \iff \lim_{n \rightarrow \infty} |p_0 - \lambda q_0|^2 \prod_{k=1}^n \left|1 - \frac{c_k}{\lambda}\right|^2 = 0.$$

Since $\lambda = \gamma_1 \lambda_\ell$ for some $\ell = 1, \dots, s-1$, $p_0 - \lambda q_0 \neq 0$ (recall that $q_0 = 1$). Furthermore, we observe that $\frac{1}{\lambda_\ell} = \overline{\lambda_\ell} = \lambda_{s-\ell}$. Consequently

$$\lim_{n \rightarrow \infty} S_n(\gamma_1 \lambda_\ell) = 0 \iff \prod_{k=1}^{\infty} \left| 1 - \frac{\lambda_{s-\ell}}{\gamma_1} c_k \right|^2 = 0.$$

Since the single factor in the product has the form

$$\left| 1 - \frac{\lambda_{s-\ell}}{\gamma_1} c_k \right|^2 = 1 - 2 \frac{c_k}{\gamma_1} \cos \left(\frac{2(s-\ell)\pi}{s} \right) + \left(\frac{c_k}{\gamma_1} \right)^2 = 1 - 2 \frac{c_k}{\gamma_1} \cos \left(\frac{2\ell\pi}{s} \right) + \left(\frac{c_k}{\gamma_1} \right)^2,$$

we see that for all $k \geq 1$ it assumes the minimum for $\ell = 1$. With that and (9) in mind, we can conclude that $\gamma_1 \lambda_1$ is not an eigenvalue iff $\gamma_1 \lambda_\ell$ are not eigenvalues for any $\ell = 1, 2, \dots, s-1$ which leads to

$$(10) \quad B_s^{(\mathbf{p})} \text{ is not injective} \iff \prod_{k=1}^{\infty} \left| 1 - \frac{\lambda_1}{\gamma_1} c_k \right|^2 = 0 \text{ and } \lim_{n \rightarrow \infty} S_n^*(\gamma_1 \lambda_1) < \infty.$$

Thus we need to examine if the condition

$$0 = \prod_{k=1}^{\infty} \underbrace{\left(1 - 2 \frac{c_k}{\gamma_1} \cos \left(\frac{2\pi}{s} \right) + \left(\frac{c_k}{\gamma_1} \right)^2 \right)}_{a_{k,s}}$$

is satisfied.

Note that

- $a_{k,2} = 1 + 2 \frac{c_k}{\gamma_1} + \left(\frac{c_k}{\gamma_1} \right)^2 > 1$,
- $a_{k,3} = 1 + \frac{c_k}{\gamma_1} + \left(\frac{c_k}{\gamma_1} \right)^2 > 1$,
- $a_{k,4} = 1 + \left(\frac{c_k}{\gamma_1} \right)^2 > 1$.

Thus, in these three cases the above condition does not hold. Consequently, for any distribution \mathbf{p} the operator $B_s^{(\mathbf{p})}$ is injective for $s = 2, 3, 4$.

Now consider $s \geq 5$ and a geometric distribution \mathbf{p} with parameter $p \in (0, 1)$. We choose the parameter p in such a way that $\cos \left(\frac{2\pi}{s} \right) > \frac{p}{2}$. Note that for geometric distribution $c_k = p$, $k = 1, 2, \dots$. Then

$$2 \cos \left(\frac{2\pi}{s} \right) \geq 2 \cos \left(\frac{2\pi}{5} \right) > p \geq \frac{p}{\gamma_1},$$

and thus

$$2 \frac{p}{\gamma_1} \cos \left(\frac{2\pi}{s} \right) > \left(\frac{p}{\gamma_1} \right)^2,$$

which yields

$$1 > \underbrace{1 - 2 \frac{p}{\gamma_1} \cos \left(\frac{2\pi}{s} \right) + \left(\frac{p}{\gamma_1} \right)^2}_{a_{k,s}} = \text{const.}$$

Furthermore

$$S_n^*(\gamma_1 \lambda_1) = \sum_{k=1}^n \prod_{i=0}^{k-1} \left| \frac{\gamma_1 \lambda_1 q_i - p_i}{\gamma_1 \lambda_1 q_{i+1}} \right| p_k = \sum_{k=1}^n \frac{q_0 p_k}{q_k} \prod_{i=0}^{k-1} \left| \frac{\gamma_1 \lambda_1 q_i - p_i}{\gamma_1 \lambda_1 q_i} \right| = p \sum_{k=1}^n \prod_{i=0}^{k-1} \sqrt{a_{k,s}} = p \sum_{k=1}^n (\sqrt{a_{1,s}})^k.$$

Since $a_{k,s} = a_{1,s} < 1$, we obtain that $\lim_{n \rightarrow \infty} S_n^*(\gamma_1 \lambda_1) < \infty$. Therefore (10) yields that in the case of geometric distribution \mathbf{p} with the parameter p satisfying the inequality as above $B_s^{(\mathbf{p})}$ for $s \geq 5$ is not injective. \square

In Theorem 3.1 we examined injectivity of $B_s^{(\mathbf{p})}$ with domain $D(B_s^{(\mathbf{p})}) \subset \mathbb{C}^\infty$, but for the purposes of the problem we should only consider the injectivity or its lack on $D(B_s^{(\mathbf{p})}) \cap \mathbb{R}^\infty$. Of course, injectivity on $D(B_s^{(\mathbf{p})}) \subseteq \mathbb{C}^\infty$ implies injectivity on $D(B_s^{(\mathbf{p})}) \cap \mathbb{R}^\infty$. Consequently, it follows from Theorem 3.1 that for any

\mathbf{p} the operator $B_s^{(\mathbf{p})}$ is injective in $D(B_s^{(\mathbf{p})}) \cap \mathbb{R}^\infty$ for $s = 2, 3, 4$. The opposite implication may not be true in general but in the case we consider it turns out that it holds.

Theorem 3.2. *For any \mathbf{p} the operator $B_s^{(\mathbf{p})}$ is injective on $D(B_s^{(\mathbf{p})}) \cap \mathbb{R}^\infty$ iff $s \in \{2, 3, 4\}$.*

Proof. As already mentioned the implication " \Leftarrow " is an immediate consequence of the same implication from Theorem 3.1.

We will prove the opposite implication by contradiction, i.e. we will show that there exists a distribution \mathbf{p} such that for $s \geq 5$ the operator $B_s^{(\mathbf{p})}$ is not injective in $D(B_s^{(\mathbf{p})}) \cap \mathbb{R}^\infty$. Let $s \geq 5$ and $\mathbf{p} = (p_k)_{k=0}^\infty$ be geometric distribution with parameter $p \in (0, 1)$ such that $\cos(\frac{2\pi}{5}) > \frac{p}{2}$. Then, from the proof of Theorem 3.1, we obtain that $\gamma_1 \lambda_1, \gamma_1 \bar{\lambda}_1$ are eigenvalues of A . We denote a non-zero eigenvector attached to $\lambda = \gamma_1 \lambda_1$ by $\mathbf{x} = (x_0, x_1, \dots)$ and the vector with conjugate entries by $\bar{\mathbf{x}} = (\bar{x}_0, \bar{x}_1, \dots)$.

We will first note that \mathbf{x} cannot be of the form $\mathbf{x} = i\mathbf{y}$ for a vector $\mathbf{y} \in \mathbb{R}^\infty$. Indeed, in such a case we would have $A\mathbf{y} = \lambda\mathbf{y}$ which is impossible since λ is not a real number.

Note that $\bar{\mathbf{x}}$ is an eigenvector of A attached to the eigenvalue $\bar{\lambda}$, because

$$A\bar{\mathbf{x}} = \overline{A\mathbf{x}} = \overline{\lambda\mathbf{x}} = \bar{\lambda}\bar{\mathbf{x}},$$

where the first equality holds since A is a matrix with real entries. Consider

$$B_s^{(\mathbf{p})} \mathbf{x} = \prod_{k=1}^{s-1} (A - \gamma_1 \lambda_k I) \mathbf{x}.$$

Now, due to the fact that $(A - \gamma_1 \lambda_k I)$ and $(A - \gamma_1 \lambda_\ell I)$ commute, we obtain:

$$B_s^{(\mathbf{p})} \mathbf{x} = \left(\prod_{k=2}^{s-1} (A - \gamma_1 \lambda_k I) \right) (A - \gamma_1 \lambda_1 I) \mathbf{x} = \prod_{k=2}^{s-1} (A - \gamma_1 \lambda_k I) \mathbf{0} = \mathbf{0}.$$

The fact that, say, $\bar{\lambda}_1 = \lambda_{s-1}$ and that $\bar{\mathbf{x}}$ is an eigenvector of A respective to $\bar{\lambda}$ yield

$$B_s^{(\mathbf{p})} \bar{\mathbf{x}} = \prod_{k=1}^{s-2} (A - \gamma_1 \lambda_k I) (A - \gamma_1 \lambda_{s-1} I) \bar{\mathbf{x}} = \prod_{k=1}^{s-2} (A - \gamma_1 \lambda_k I) \mathbf{0} = \mathbf{0}.$$

Fix $\mathbf{z} = \mathbf{x} + \bar{\mathbf{x}} \in \mathbb{R}^\infty$. Note that $\mathbf{z} \neq \mathbf{0}$, because as it has already been observed, \mathbf{x} cannot have all entries which are purely imaginary. Finally,

$$B_s^{(\mathbf{p})} \mathbf{z} = B_s^{(\mathbf{p})} (\mathbf{x} + \bar{\mathbf{x}}) = B_s^{(\mathbf{p})} \mathbf{x} + B_s^{(\mathbf{p})} \bar{\mathbf{x}} = \mathbf{0}.$$

Hence $B_s^{(\mathbf{p})}$ is not injective in $D(B_s^{(\mathbf{p})}) \cap \mathbb{R}^\infty$ for $s \geq 5$. □

4. CONCLUSION

The above considerations on injectivity of $B_s^{(\mathbf{p})}$ lead to the following correction to the result proposed in LB and recalled in Theorem 2.1.

Proposition 4.1. *The assertion of Theorem 2.1 holds true when $\gamma_1 < 1$ (that is, $N < \infty$) for any $s \geq 1$. For $\gamma_1 \geq 1$ (that is, $N = \infty$) the assertion of Theorem 2.1 holds true for $s \in \{1, 2, 3, 4\}$.*

Proof. It is well known (see Section 1) that the result for $s = 1$ holds true. The proof in the case $\gamma_1 < 1$ (which implies $N < \infty$) given in LB is correct since in this case the operator $B_s^{(\mathbf{p})}$ is invertible for any $s \geq 2$. For $\gamma_1 \geq 1$ (which implies $N = \infty$) due to Theorem 3.2 we have injectivity of $B_s^{(\mathbf{p})}$ for $s \in \{2, 3, 4\}$ therefore the method of the proof proposed in LB is correct and thus the respective part of the assertion from Theorem 2.1 holds true. □

Finally, let us emphasize that for $\beta_1 \geq 1$ and $s \geq 5$ it follows from Theorem 3.1 that $B_s^{(\mathbf{p})}$ may not be injective for some distributions $\mathbf{p} \in \mathcal{M}_s$, even such that appear in the conclusion of Theorem 2.1 (the geometric law was identified as such in the proof of Theorem 3.1) and thus the argument used in LB is no longer valid. **Therefore the problem of characterization of the parent distribution of the sequence of iid observations from the discrete distribution by the condition $\mathbb{E}(W_{i+s}|W_i) = \beta_1 W_i + \beta_0$ for $\beta_1 \geq 1$ and $s \geq 5$ remains open!**

Acknowledgement. We are very thankful to referees for their remarks which helped us a lot in improving presentation of the material of the paper. It will appear in *Statistics*.
